

**Paint Lakes
Sockeye Salmon Enhancement
Progress Report
2003**

**Prepared by:
Trenten T. Dodson, Biologist
March 2004**

This year's operation of the Paint Lake Sockeye Salmon Enhancement Project was made possible through enhancement taxes paid by the commercial fishermen in Area H, Cook Inlet and associated waters, through the harvest and sale of surplus fish and by a grant from the U.S. Fish and Wildlife Service.

DISCLAIMER

The Cook Inlet Aquaculture Association conducts salmon enhancement and restoration projects in area H, Cook Inlet and associated waters. As an integral part of these projects a variety of monitoring and evaluation studies are conducted. The following progress report is a synopsis of the monitoring and evaluation studies conducted for the Paint Lake sockeye salmon enhancement project.

The purpose of the progress report is to provide a vehicle to distribute the information produced by the monitoring and evaluation studies. Data collected each year are presented with a summary of the information previously collected for comparative purposes. These reports are intended to provide a general description of project activity and are not an exhaustive evaluation of any restoration or enhancement project. The information presented in this report has not undergone an extensive review. As reviews are completed, the information may be updated and presented in later progress reports.

ACKNOWLEDGEMENTS

Many individuals contributed to the successful 2003 field season at the Paint Lake Salmon Enhancement Project. Appreciation is extended to Cook Inlet Aquaculture Association seasonal employees, Tyler Staples and Craig King, and full time staff, Gary Fandrei and Ronald Carlson, who endured many long hours in the field. The Cook Inlet Aquaculture Association Board of Directors and the Alaska Department of Fish and Game for the support they have provided to the Paint Lakes Sockeye Salmon Enhancement Project. Finally, thank you to the U.S. Fish and Wildlife Service and Senator Ted Stevens for providing the funding that allowed us to increase our evaluation of this important salmon resource.

ABSTRACT

Upper and Lower Paint Lakes are located in the McNeil River State Game Refuge approximately 178 kilometers southwest of Homer, Alaska. The main tributary of the system is Upper paint Creek; the outlet, from the lower lake is the Paint River, which flows approximately 16 km to Akjemguiga Cove of Kamishak Bay of Cook Inlet. Initial salmon enhancement activities were conducted by ADF&G. The Cook Inlet Aquaculture Association (CIAA) began enhancement at the Paint Lakes in 1991 after the completion of the Paint River Fish Ladder.

Between 14 October and 11 November 2002, an estimated .508 million sockeye salmon (*Oncorhynchus nerka*) pre-smolt were released into Upper Paint Lake. All .508 million fry were otolith marked. There were no sockeye salmon fry or presmolt released to Upper or Lower Paint Lake in 2003

During 2003, smolt migration monitoring began on 20 May and continued daily until 11 July. During this time a total of 6,865 sockeye salmon smolts migrated from the lake.

Based on otolith marks, 100% of the migrating sockeye smolts were enhanced and all smolts were age 1 . The average length and weight of the sockeye smolts was 95 mm (± 1.5 mm) and 7.9 g (± 0.46 g).

INTRODUCTION AND PURPOSE

Sockeye salmon is the only species that has been stocked on a production scale within the Paint River system. Paint River Lakes were stocked with hatchery sockeye fry on a near annual basis from 1986 through 1996. However, extremely low returns of 200 to 1,800 fish per year were documented. Currently, there are no definite explanations for the poor survivals from the Paint River system. Other nearby lakes in the Kamishak District, stocked with the same size fry at the same basic time period, have produced fair to excellent returns of adult sockeye salmon. Unfortunately, little evaluation work has been conducted to date to attempt to answer these possible reasons for poor sockeye production from the Paint River system.

In 1991, CIAA constructed a \$2.5 million fish pass on the Paint River. The purpose of the fish pass was to provide anadromous fish access to spawning and rearing habitats available in the Paint River system. The Paint River fish pass, however, has never been operated because adult returns from the initial enhancement efforts were too small to warrant the operation of the pass and CIAA redirected its financial resources to maintain enhancement efforts initiated by the State (excerpt Trail Lakes Annual Management Plan 2002, Amendment A).

CIAA, the State and the Federal government have all invested in the development of a Paint River fishery and CIAA is currently seeking additional funds to complete the Paint River fish pass. The scope of this evaluation was to assess the success of the October presmolt release by monitoring smolt migration, zooplankton density, and other limnological parameters.

PROJECT AREA

Upper and Lower Paint Lakes are located in the McNeil River State Game Refuge approximately 178 kilometers southwest of Homer, Alaska. The two lakes are connected by a small creek. The main tributary of the system is Upper Paint Creek; the outlet, at the lower lake forms a falls to the Paint River, which flows approximately 16 km to Akjemguiga Cove of Kamishak Bay of Cook Inlet.

Figure 1. Area Map of Upper Paint Lake.

Figure 2. Area Map of Lower Paint Lake.

Fish present in the Paint Lakes watershed include lake trout (*Salvelinus namaycush*) and arctic grayling (*Thymallus arcticus*), and round white fish (*Prosopium cylindraceum*).

METHODS

In general, sockeye salmon egg takes hatchery incubation, fry rearing, and smolt enumeration monitoring follow procedures recommended by ADF&G.

Limnological Sampling and Environmental Conditions

During 2003, assessments of water quality were conducted three times during the open water season from May to August. Two sites, one on each lake (See Figures 1 and 2, black circles), were sampled for dissolved oxygen, temperature and light transmission profiles, Secchi disk transparency, and zooplankton densities. Samples for analysis of phosphorous, carbon, chlorophyll a, phaeophytin a, nitrogen, calcium, magnesium, iron, conductivity, pH, alkalinity, turbidity, and color were also collected with a Kemmerer sampler one meter below the surface and from the midhypolimnion.

Water samples were collected by CIAA and water analysis completed by ADF&G. Sample collection and analysis procedures are described by Koenings, et al. (1986).

Percent cloud cover was estimated, precipitation measured to the nearest millimeter and lake water and air temperatures were recorded at 5:00 PM each day by CIAA as part of the smolt enumeration activities. Standard CIAA procedures were followed for collecting these measurements.

Smolt Enumeration

To enumerate the smolt migration, a smolt trap was temporarily placed at the outlet of Lower Paint Lake. The smolt trap consisted of a modified fyke net with nylon mesh leads extended with Vexar® netting and a double compartment live-box. The leads and fyke net funneled migrating

smolts into the live-box. A swing gate controlled by the trap operators directed smolts into one of two live-box compartments where they were counted and released downstream, momentarily held for a sub-sample count, or passed through the trap system uncounted.

Total counts of smolts migrating from the Paint Lakes were made until the migration of fish exceeded 1,000 to 2,000 fish per hour. At migrations rates greater than 2,000 fish per hour, fish densities in the trap become too great and the fish become stressed. To avoid stressing the fish during periods of peak migration, a 10% sub-sampling procedure was used to enumerate the fish.

To enumerate migrating smolts with the 10% sub-sampling procedure, the counting period was divided into 20-minute intervals. During each 20-minute interval, migrating fish were directed into the live-box for two minutes and then counted. During the remaining 18 minutes, migrating smolts passed through the trap uncounted. To estimate the number of smolts migrating during the 20-minute interval, the two-minute smolt count was multiplied by 10.

Assuming the two-minute sub-sampling intervals were randomly distributed throughout sub-sampling¹ and smolts moved through the weir randomly, the total smolt migration was estimated as follows:

If:

T_c = number of fish counted with the total count procedure,

\hat{T}_s = number of fish counted with the 10% sub-sampling procedure,

\hat{T} = the total smolt migration,

y = the number of fish counted in each two minute sub-sampling interval,

n = the number of two minute sub-sampling intervals sampled, and

N = the number of possible two minute sub-sampling intervals,

Then, the total smolt migration (\hat{T}) is:

$$\hat{T} = T_c + \hat{T}_s;$$

with a variance of:

¹ Predetermined randomly selected 2-minute sub-sampling intervals assured random distribution within each 20-minute period.

$$v(\hat{T}_s) = N^2((N - n) / N) \sum (y_i - \bar{y})^2 / (n(n - 1));$$

and 95% confidence limits of:

$$\hat{T}_s \pm 2\sqrt{v(\hat{T}_s)}.$$

The variance about the estimated smolt migration, \hat{T} , is equal to the variance about \hat{T}_s , because T_c is a total count with 0 variance.

In 2003, migrating smolts were enumerated from 20 May through 11 July. The 10% sub-sampling procedure was not used in 2003. A detailed description of smolt enumeration procedures is available in any of CIAA's Enhancement Project Procedure Manual (CIAA, 2002).

Smolt Characteristics and Enhanced Contribution

CIAA has released sockeye salmon fry to Upper and Lower Paint Lakes in 1995 and 1996. However, this is the first year the smolt migration was enumerated by CIAA. The smolt characteristics and enhanced contribution were assessed by collecting a sample of the migrating sockeye and coho smolts to collect an otolith and determine the smolts' age, weight, and length characteristics.

In 2002, CIAA marked the otolith of all salmon fry released to the Paint Lakes with a thermal mark². The purpose of this mark is to determine the contribution of released fish to the smolt population. In 2003, the otoliths of sockeye smolts collected for age, weight and length measurements were removed and checked for a thermal mark.

In 2003, smolts collected for measurement and otolith removal were sampled in proportion to the daily smolt migration. This was attempted by collecting every 450th sockeye smolt. The numbering sequence began when the first fish passed through the trap and continued consecutively until the smolt migration was complete. However, due to the unexpected low

² The otolith mark is a hatchery induced thermal band produced by controlled temperature changes during incubation.

number of migrating smolts, the method was changed to collect 5 samples every day. Age, weight and length measurements were made on and otoliths removed from 58 sockeye smolts.

Each smolt collected for evaluation was first measured to the nearest millimeter for fork length³ and then weighed to the nearest 0.1 gram. Several scales were also removed from the primary growth area⁴ and mounted on a glass slide for subsequent age determination. The otoliths were then removed and placed in a labeled one-dram vial. Ethanol was added to the vial to cover the otoliths.

After the smolt migration was complete, the otoliths were shipped to Trail Lakes Hatchery. Staff at Trail Lakes Hatchery processed the otoliths and checked each for a hatchery mark following procedures described by Glick and Shields (1993). Of the 58 pairs of sockeye otoliths collected, 58 were readable.

Sockeye smolt characteristics, the proportion of enhanced sockeye smolt and the proportion of age 1 and 2 sockeye smolt in the migrating population, were estimated with the following notations and formulas provided by ADF&G.

If:

N = total number of migrating smolts,

N_h = number of smolts in stratum h , ($N = \sum N_h$),

n = total number of smolts sampled,

n_h = number of smolts sampled in stratum h , ($n = \sum n_h$),

a = total number of enhanced smolts sampled,

a_h = number of enhanced smolts sampled in stratum h , ($a = \sum a_h$),

$p_h = a_h / n_h$, the proportion of enhanced smolts in stratum h ,

$q_h = 1 - p_h$, the proportion of wild smolts in stratum h ,

c_i = number of age = i smolts sampled,

³ Standard fork length was measured from the tip of the snout to the fork of the tail.

c_{hi} = number of age = i smolts sampled in stratum h , ($c_i = \sum c_{hi}$),

$l_{hi} = c_{hi} / n_{hi}$, the proportion of age = i smolts in stratum h ,

$m_{hi} = 1 - l_{hi}$, the proportion of other than age = i smolts in stratum h ,

$f = n / N$, the sampling fraction (assumed equal in all strata),

$W_h = N_h / N$, the stratum weight, and

$y =$ the weight or length of the smolt.

Then, the proportion of enhanced smolts, \hat{P} , is:

$$\hat{P} = a / n;$$

with a variance of:

$$v(\hat{P}) = (1 - f)(1/n) \sum W_h p_h q_h;$$

which, under proportional allocation, is like the usual simple random sample estimate.

And, the total number of enhanced smolts, \hat{A} , is:

$$\hat{A} = N(a / n) = N\hat{P};$$

with a variance of:

$$v(\hat{A}) = N^2(1 - f)(1/n) \sum W_h p_h q_h = N^2 v(\hat{P}).$$

Since samples sizes are large and \hat{P} is not extreme, the normal approximation without a correction for continuity, can be used to develop the relative error. Thus, the 95% confidence interval estimates for \hat{P} and \hat{A} are:

$$\hat{P} \pm 1.96\sqrt{v(\hat{P})} \quad \text{and} \quad \hat{A} \pm 1.96\sqrt{v(\hat{A})};$$

with relative errors of:

$$\left(1.96\sqrt{v(\hat{P})}/(\hat{P})\right)100 \quad \text{and} \quad \left(1.96\sqrt{v(\hat{A})}/(\hat{A})\right)100.$$

The proportion of age = i smolts in the migration was also estimated as:

$$\hat{L}_i = c_i / n;$$

with a variance of:

⁴ The primary growth area is located above the lateral line on a diagonal from the posterior insertion of the dorsal fin to the anterior insertion of the anal fin.

$$v(\hat{L}_i) = (1-f) \frac{1}{n} \sum_h W_h L_{hi} m_{hi};$$

and, the total number of age = i smolts was estimated as:

$$\hat{C}_i = N(\hat{L}_i);$$

with a variance of:

$$v(\hat{C}_i) = N^2 v(\hat{L}_i).$$

Confidence intervals (95%) estimates for age-class proportion and abundance, assuming 2 age-classes, are:

$$\hat{L}_i \pm 2.24 \left(\sqrt{v(\hat{L}_i)} \right) \quad \text{and} \quad \hat{C}_i \pm 2.24 \left(\sqrt{v(\hat{C}_i)} \right).$$

Mean weight or length of age = i smolt was also estimated as:

$$\bar{y}_i = \frac{\sum_h \sum_j y_{hij}}{c_i};$$

with an approximate variance estimate of:

$$v(\bar{y}_i) \cong \frac{1}{\hat{C}_i^2} \sum_h \frac{N_h^2 (1-f)}{n_h (n_h - 1)} \left[\sum_j (y_{hij} - \bar{y}_{hi})^2 + c_{hi} (1 - c_{hi}/n_h) (\bar{y}_{hi} - \bar{y}_i)^2 \right];$$

and 95% confidence interval estimates of:

$$\bar{y}_i \pm 1.96 \left(\sqrt{v(\bar{y}_i)} \right).$$

Adult Return and Escapement

Adult salmon returning to Paint River Falls is enumerated annually by ADF&G aerial surveys. Currently, the Paint River Fish Ladder is not operating and there is no escapement of sockeye salmon (or any other species of salmon) into the Paint Lake system.

Gamete Collection, Incubation and Rearing

Gamete collecting activities for the Paint Lake System are not active. However, in 2002, Trail Lakes Hatchery experienced a surplus of Tustumena Lake sockeye salmon fry. These fry were reared at the hatchery to the presmolt stage for release to the Paint Lake System.

Fish Transport and Stocking

A Total of .508 million sockeye salmon presmolt produced from gametes collected from Tustumena Lake in 2001 were released to Upper Paint Lake on 14, 16, 17 October and 8 November 2002 (Table 1). The presmolt were transported by truck in oxygenated tanks from Trail Lakes Hatchery to the Soldotna Airport and gravity fed via tubing into an agriculture airplane. They were then flown to Upper Paint Lake and dropped from 100ft into the water. None of the released fry were externally marked or tagged; however, the otoliths of all the released fry were marked with thermal bands [Rbr 1:1.3,2.3]. Otoliths samples were processed to document the marks and are on file at Trail Lakes Hatchery.

Table 1. Summary of sockeye salmon releases at the Paint Lakes, 1994 - 2003.

RESULTS AND DISCUSSION

Limnology and Environmental Conditions

Water Chemistry and zooplankton data from 2003 are presented in Appendix 1. Historical zooplankton densities presented as seasonal means are presented in Table 2.

Environmental conditions during the Paint Lake smolt migration were monitored from 21 May to 11 June 2003. Stream stage measurements averaged 0.55 feet and ranged from 0.19 to 1.11 feet. During the period of smolt migration, stream temperatures averaged 12.7°C and ranged from 9 to 19°C. Air temperatures averaged 21.8°C and ranged from 7 to 28°C. Twelve percent of the days were clear, 55% partly cloudy, and 33% were completely overcast. A total of 177 mm of rain fell during this period (Appendix 2).

Smolt Enumeration

In 2003, a total of 6,865 sockeye smolts migrated from the lake (Appendix 3). The peak of the 2003 smolt migration occurred about 19 June (See Recommendations).

Smolt Characteristics and Enhanced Contribution

In 2003, characteristics of the smolt migration were evaluated from scale samples collected throughout the migration and from measurements of length and weight. Based on these samples and measurements, all migrating sockeye salmon smolts were age 1 and of hatchery origin. The average length and weight of the age 1 sockeye smolts were 95 mm (± 1.5 mm) and 7.9g (± 0.46 g). (Table 3).

Table 3. Age structure, length, and weight characteristics of the Paint Lakes sockeye smolt, 2003

| Smolt Year | Age Class (%) | | | | Mean length (mm) | | | | Mean weight (g) | | | |
|---------------|---------------|------|-----|------|------------------|---------------|-----|------|-----------------|----------------|-----|------|
| | Age | 95% | Age | 95% | Age | 95% | Age | 95% | Age | 95% | Age | 95% |
| | 1.0 | C.I. | 2.0 | C.I. | 1.0 | C.I. | 2.0 | C.I. | 1.0 | C.I. | 2.0 | C.I. |
| 2003 | 100 | - | 0 | - | 94.7 | (± 1.5) | - | - | 7.94 | (± 0.46) | - | - |

In 2003, the proportion of hatchery-incubated fry in the sockeye smolt migration was 100% as expected (Table 4).

Table 4. The contribution of enhanced sockeye to the Paint Lakes smolt migration, 2003

| Smolt Year | Total | | Number | | % Hatchery | |
|---------------|-------|-------------|--------|----------|------------|-------------|
| | No. | 95% C.I. | Wild | Hatchery | % | 95% C.I. |
| 2003 | 6,865 | - | - | 6,865 | 100 | - |

*All smolts are or hatchery origin. There is no native population of sockeye salmon.

Adult Return & Escapement

Sockeye salmon have been returning to the Paint River since 1989, though none have been able to migrate up the river to the lakes. Table 5 displays the annual rerun to the falls at Paint River.

Table 5. Annual sockeye salmon return to Paint River Falls, 1989-2003

| Year | Number of Adults |
|---------|------------------|
| 1989 | 150 |
| 1990 | 0 |
| 1991 | 700 |
| 1992 | 300 |
| 1993 | 800 |
| 1994 | 550 |
| 1995 | 250 |
| 1996 | 200 |
| 1997 | 400 |
| 1998 | 1,870 |
| 1999 | 900 |
| 2000 | 30 |
| 2001 | 75 |
| 2002 | 30 |
| 2003 | 0 |
| Total | 6,255 |
| Average | 417 |

Currently, the Paint River Fish Ladder is not operating; thus, there is no salmon escapement to the Paint Lakes.

Special Studies

On 21 October, a hydroacoustics survey of Upper and Lower Paint Lake was conducted by ADF&G and CIAA. The purpose of the survey was to determine if smolts had remained in the lake system; and would emigrate the following year. The survey showed that the sockeye salmon were not present within the Lake (See Attached Report). Therefore, there will be no smolt migration study done in 2004.

RECOMMENDATIONS

The mid-October fry release was designed to by-passed the summer rearing period and to avoid predation by lake trout and grayling. However, the large size of the presmolt may have allowed them to emigrate from the lakes soon after release, or earlier in the spring than expected. (The 3.6 gram presmolt release size is approximately the same as age 1 sockeye smolt migrating from Kirschner Lake, approximately 25 miles northeast of Upper Paint Lake). Therefore, the amount of smolts collected at the smolt trap does not definitively reflect the actual survival and success of the October release program. Future returns to the Paint River Falls could help provide extra data for determining the success of the program. Further investigations are recommended and modifications to the evaluation program should be initiated.

Appendix 3. Paint Lakes 2003 - Project Update.

2003 Paint Lake Project Update

Stocking & Misc. Activities

| | |
|----------------|--------|
| Crew on-site: | 20-May |
| Ice-out: | ND |
| Crew off-site: | 14-Jul |
| Fry Release: | None |

Smolt Migration

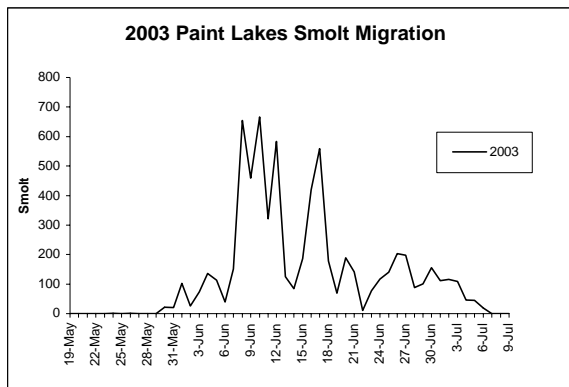

| | | |
|-------------------|------------------|-------|
| Dates: | 20-May to 12-Jul | |
| Sockeyes: | | 6,865 |
| Mortalities: | | 0 |
| Percent age 1: | | 100% |
| Percent age 2: | | 0% |
| Percent hatchery: | | 100% |

Egg Take

| | |
|-------------------------|--|
| Dates: | |
| No. of broodstock used: | |
| Green eggs: | |
| Fecundity: | |
| Eyed eggs: | |
| Survival: | |

Adult Migration

| | |
|-----------------------|--|
| Dates: | |
| Sockeye total return: | |
| Paint River Return: | |
| Sport/PU Harvest: | |
| Commercial Harvest: | |
| Paint Lakes Return: | |

3/16/2004
